The amount of residual stresses may point to one solution, while the distribution of stresses may suggest other required processing alterations. Depending on the production method, changes in material, temperature, cooling rates, airflow, gate placement, part thickness, and numerous other factors will cause variations in residual stresses or their distribution throughout a plastic part.

Residual stresses are those stresses that remain in an object (in particular, in a welded component) even in the absence of external loading or thermal gradients. In some cases, residual stresses result in significant plastic deformation, leading to warping and distortion of an object. In others, they affect susceptibility to fracture and fatigue.

Here are some factors that cause residual stress in plastic parts:
1. Thermoplastics are long-chain molecules. Their resting or stress-free state is a coiled chain something like a slinky.

Clear plastics are used extensively in the production of lenses and optical transparencies. Residual stresses introduce birefringence—an asymmetry of the index of refraction—that can make a plastic lens unable to focus properly. Even a small level of birefringence hampers optical properties and product performance.

Residual Stress Testing for Transparent Polymers ...

The quality of molded parts made of clear thermoplastic polymers is determined by the absence or presence of residual stresses. In this work we analyzed the flow-induced residual stresses, which cause serious damage to plastic parts used in automotive and optical applications.

Residual strain is the permanent deformation that remains after removing the stress from a test sample. This deformation can be important for product design and material selection. Standard mechanical test procedures do not take into account the condition of the specimen after stress has been removed.
